

# **Therapeutic Drug Levels for Tb: When and Why**

**Scott K. Heysell MD, MPH, Jane Moore RN, MHSA,  
Dorothy Bunyan, Eric Houpt MD**

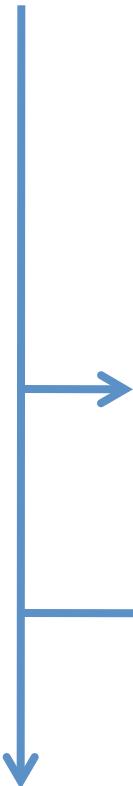

## The Problem

- Slow response to tuberculosis (TB) treatment leads to prolonged infectiousness, may increase the likelihood of acquired drug resistance and extends treatment duration
- Our assumption is low drug levels is a contributor to slow response, at least in some patients
- Since 2007, initiative for patients slow to respond to TB therapy to have therapeutic drug level monitoring

## Methods

- All adults treated for pulmonary TB from 3/1/07-5/1/09
- ≥18 years, culture-positive, started on first-line TB regimen; excluded if drug monitoring for other reasons, or if TB isolate resistant to one or more first-line drugs
- Slow response- After 4 weeks of therapy: two or more of the following-
  - 1. persistent TB symptoms, 2. positive sputum smear, 3. no improvement in chest x-ray
- Drug levels drawn at 2 hrs after observed morning dose of all medications, serum separated and sent on ice to referral laboratory in Florida for HPLC.

350 patients treated for drug-susceptible PTB

37 patients with initial TB isolate  
resistant to one or more first-line agents

2 patients with TDM performed for  
reasons other than slow response

**311** patients included

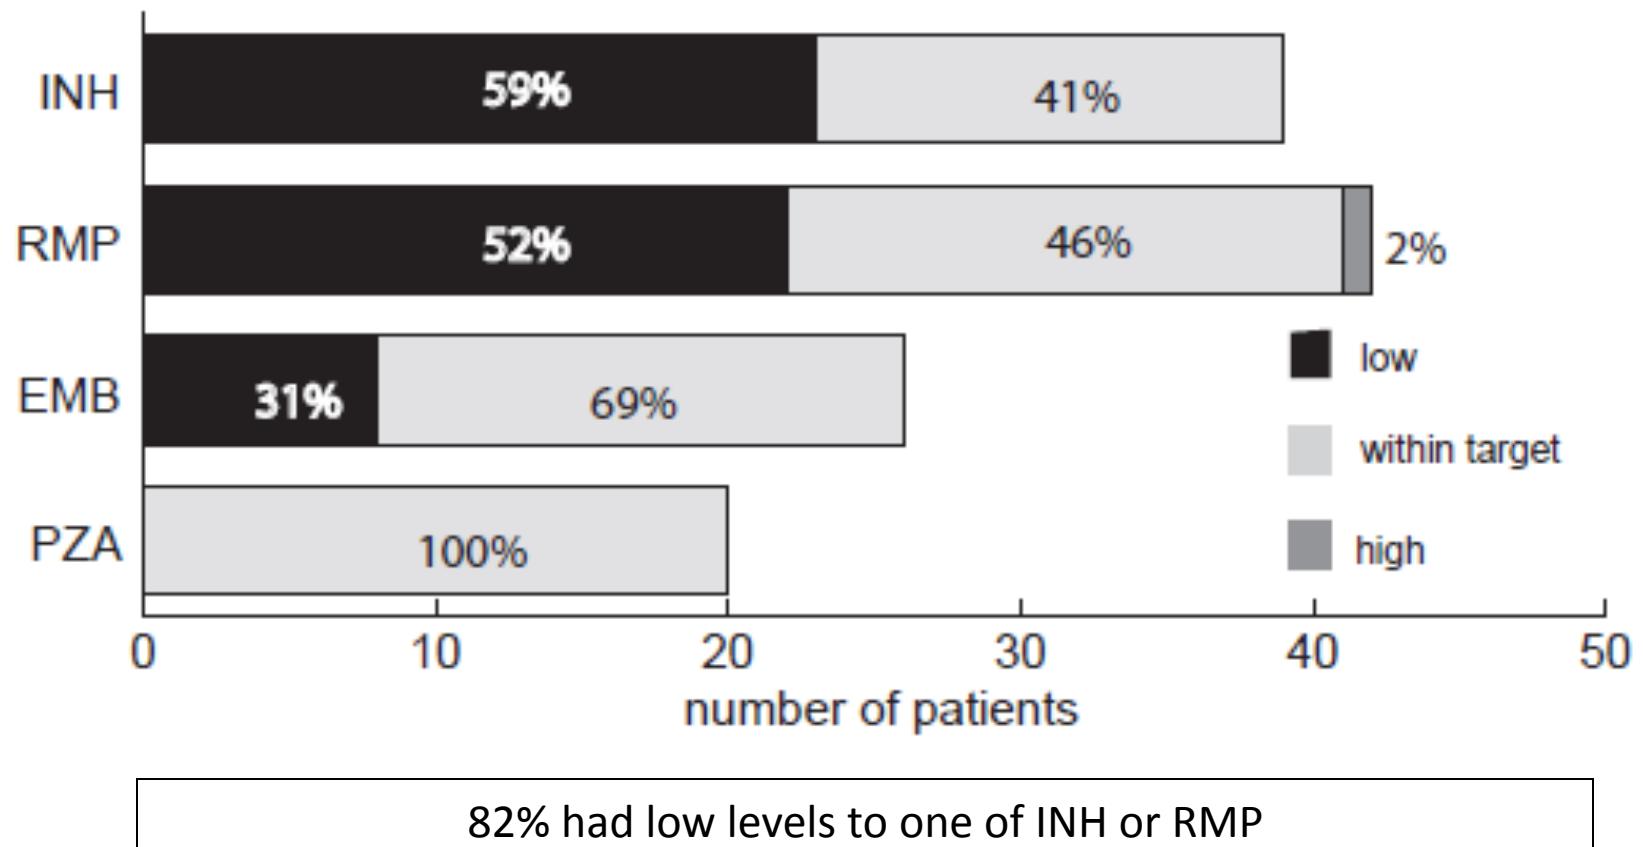

**42 (14%)** met criteria for slow  
response

## Diabetes is a risk factor for slow response

|   | Total<br>N= 311 (%) | Slow response<br>N=42 (%) | Normal response<br>N= 269 (%) | Risk Ratio<br>[95% CI] p-value    |

## Summary-1

- Drug level monitoring for INH and RMP may be a useful adjunct in Tb patients who are responding slowly to treatment

**Figure 1. Obtaining a sample for TDM**

## Summary-1

- Drug level monitoring for INH and RMP may be a useful adjunct in Tb patients who are responding slowly to treatment
- We expect to find low levels to INH or RMP in many, and thus have created guidelines

**Table 1. Indication and timing of therapeutic drug monitoring (TDM) in clients slow-to-respond**

| Reason for TDM   | Drugs to check      |
|--|---------------------|
| 1. In any client with slow response at 4-6 weeks of treatment suggested by either or both of the following: <ol style="list-style-type: none"><li>a. For clients with smear positive pulmonary TB, sputum smear (+) not decreasing [adequate decrease is 4+ to 2+; 3+ to 1+; or 2+/1+ to smear negative]</li><li>b. no improvement in TB symptoms (e.g. no weight gain, no reduction in cough, persistent fever, or worsening of chest x-ray if performed)</li></ol> | Isoniazid, Rifampin |

## Summary-2

- If levels are low:

**Table 2. Isoniazid and Rifampin expected peak concentrations and usual dose adjustment\***

| Medication (expected C <sub>max</sub> range<br>in µg/ml) | Client Serum Result   | Dose adjustment   |
|--|---|---|
| ▪ Isoniazid / daily (3-6) /<br>biweekly (9-18)           | If client is on daily therapy and<br>serum level is <2            | Increase daily dose to 450 mg<br>from 300 mg                                    |
| ▪ Rifampin (8-24)  | If client is on biweekly therapy and<br>serum level is <7         | Increase biweekly dose to<br>1200 mg from 900 mg                                |
|  | If serum level is <6 (for both daily<br>and intermittent therapy) | Increase dose to 900 mg from<br>600 mg (both daily and<br>intermittent therapy) |

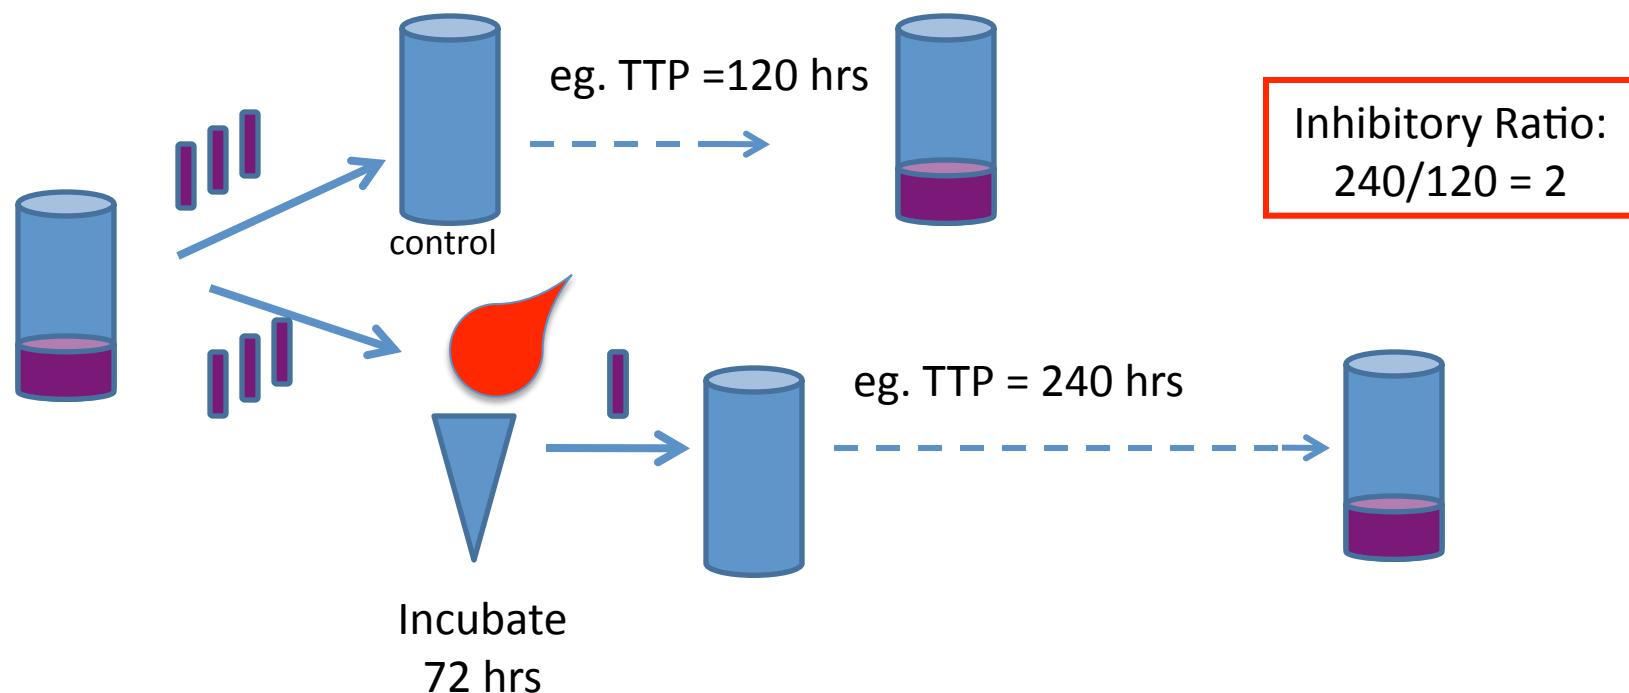

## **Summary-3**

- Additionally, we are now starting an initiative to collect INH/RMP levels on all diabetics at the start of therapy (2 weeks)

## Summary-4

- Finally, we are trying to understand why serum drug levels are not perfectly predictive
  - many individuals with low levels will do fine
  - not all slow responders will have low levels

Part of this is likely because the blood tells you about the drugs, but not the bug

## **Summary-4**

- Finally, we are trying to understand why serum drug levels are not perfectly predictive
  - many individuals with low levels will do fine
  - not all slow responders will have low levels

Part of this is likely because the blood tells you about the drugs, but not the bug

Thus, we have an approved protocol to receive from Florida left-over serum, and to receive from DCLS the Tb isolate

We need to get permission from the client, during or after you collect the serum

Will not affect their care, no extra blood draw, etc.

## Summary-5

### GUIDELINES FOR SLOW RESPONDERS

1. Client observed to have slow response as defined by VDH Guidelines for Therapeutic Drug Level Monitoring (approx 6 weeks of treatment)
2. Drug levels drawn for isoniazid and rifampin per VDH Guidelines and single dose increase with repeat levels following dose adjustment

### DIABETES

1. Diabetes documented upon client registry:
2. Client identified for early drug level monitoring per VDH initiative (approx 2 weeks of treatment)
3. Drug levels drawn for isoniazid and rifampin per VDH Guidelines and single dose increase with repeat levels following dose adjustment
